Business Process Explanation

Project Title: <u>Airline Flight Schedule and Delay Monitoring System</u>

Introduction

The Airline Flight Schedule and Delay Monitoring System is designed to monitor flight schedules, identify delays, and manage passenger requests when flights are delayed. The process involves four main actors: Passenger, Airline Staff, Manager, and Aviation System.

Business Process Description

The process begins when a flight delay is announced. The passenger receives a notification about the delay and reviews the available options, which include rebooking, requesting a refund, or receiving a voucher. The passenger then submits their preferred choice.

Airline staff receive the passenger's request and verify the passenger's booking details. They also check whether the request follows airline policies. If the request requires special approval, airline staff forward it to the manager.

The manager reviews exceptional requests and makes a decision to approve or reject them. The decision is communicated to the relevant staff or system for further processing.

Meanwhile, the Aviation System monitors actual flight statuses and compares them with scheduled flight information. When a delay is detected, the system records the delay, calculates its duration, and sends notifications.

The system then processes the passenger's selected option, updates the relevant flight and booking records, and sends confirmation to the passenger.

Expected Outcome

The process helps the airline monitor flight delays, manage passenger requests, maintain accurate flight records, and improve communication between passengers and airline staff.

Conclusion

The business process provides an organized way of monitoring flight delays and handling passenger requests. It also supports better flight information management through the Aviation System.
